The experimental determination of these values, apart from been laborious, is a challenge because of the low water solubility of these compounds. Using a variety of descriptors, quantitative structure-property relationships (QSPR) are explored between the experimental aqueous pK_a values of a group of fifteen benzimidazoles and descriptors calculated at the B3LYP/6-31+G(d,p) level of theory.

pK_a Definition . pK_a is the negative base-10 logarithm of the acid dissociation constant (K_a) of a solution. $\mathrm{p}K_{\mathrm{a}} = -\log_{10} K_{\mathrm{a}}$ The lower the pK_a value, the stronger the acid. For example, the pK_a of acetic acid is 4.8, while the pK_a of lactic acid is 3.8. Using the pK_a values, one can see lactic acid is a stronger acid than acetic acid.

Sometimes difficulties may arise in the experimental determination of pK_a values because it is time-consuming and requires laboratory experience. In order to improve the accuracy of pK_a predictions of the pKalc software, the further acidic and basic groups have been re-parameterized using more than 5,000 experimental aqueous pK_a values collected from the chemical literature.

Benzimidazoles are the organic compounds investigated in this work. The experimental determination of the pK_a values of protonated benzimidazoles in water is a challenge because of their low solubility. In addition, some derivatives are involved in tautomeric equilibria which increase the complexity of the theoretical pK_a determinations.
