Ceramic Microstructures

Microstructure, which is too small to be seen with the naked eye, plays an important factor in the final property of a material. For ceramics, the microstructure is made up of small crystals called grains. In general, the smaller the grain size, the stronger and denser is the ceramic material. In the case of a glass material, the microstructure is non-crystalline.

Microstructure of a typical dense ceramic. The grains are formed as the compacted grains of ceramic powder try to reduce their surface area by coalescing together during sintering. The grain boundaries are formed at the intersection of the grains and often contain impurities that form "glassy" phases.

Once fabrication flaws have been eliminated, the strain-to-failure of ceramic fibers is dominated by grain size (d), scaling as $\sim d^{-1/2}$. Typically, the grain size must be $0.1\mu\text{m}$ to $0.5\mu\text{m}$ (0.004 to 0.02 mils) to achieve the strain-to-failure goal of 0.6 percent for ceramic fibers (Evans, 1997).

Ceramography is the art and science of preparation, examination and evaluation of ceramic microstructures.

Ceramography can be thought of as the metallography of ceramics. The microstructure is the structure level of approximately 0.1 to 100 µm, between the minimum wavelength of visible light and the resolution limit of the naked eye. The microstructure includes most grains, secondary phases, grain boundaries, pores, micro-cracks and hardness microindentations. Most bulk mechanical, optical ...

Ceramography - Wikipedia
