OEM Design Engineer's Guide to Specifying Hydraulic Cylinders

A hydraulic cylinder is the actuator or 'motor' side of the system. The 'generator' side of the hydraulic system is the hydraulic pump which brings in a fixed or regulated flow of oil to the bottom side of the hydraulic cylinder, to move the piston rod upwards. The piston pushes the hydraulic oil in the other chamber back to the reservoir.

This design from System Seals provides more accurate piston and rod guidance inside the cylinder under varying load conditions. Many of the failures in a

hydraulic system show similar symptoms: a gradual or sudden loss of high pressure, resulting in the loss of power or speed in the cylinders.

How do you safely design and use hydraulic cylinders?

The hydraulic cylinder is a positive displacement reciprocating hydraulic motor, which convert the energy of a fluid into the kinetic energy of the moving piston. In other word we can say a hydraulic cylinder is a device which converts the energy of fluid which is in a pressure form in to linear mechanical force and motion.

Although hydraulic circuit layouts may vary significantly in different applications, many of the components are similar in design or function. The principle behind most hydraulic systems is similar to that of the basic hydraulic jack. Oil from the reservoir is drawn past a check ball into the piston type pump during the piston's up-stroke.
