The Influence Of Pregelatinized Starch Disintegrants

Starch gelatinization is a process of breaking down the intermolecular bonds of starch molecules in the presence of water and heat, allowing the hydrogen bonding sites to engage more water. This irreversibly dissolves the starch granule in water. Water acts as a plasticizer. Three main processes happen to the starch granule: granule swelling, crystallite or double helical melting, and amylose leaching. During heating, water is first absorbed in the amorphous space of starch, which leads to a swe

Herman and Remon (1989) have investigated the effect of many parameters on the sustained release properties of pregelatinized starch and have found that the ratio amylose/amylopectin is the most important factor influencing swelling characteristics and in vitro drug release rate. Tablets based on pregelatinized starch (25% amylose w/w) are divided into several pieces, increasing the contact surface with the dissolution medium and leading to faster drug release.

An alternative to native corn starch or polymers for wet granulations is pregelatinized starch. This is a starch that has been previously gelatinized and dried to powder form. Functionally, pregelatinized starches are split into two groups, fully pregelatinized and partially pregelatinized.
