Basic Uv Vis Theory Concepts

The Principle of UV-Visible Spectroscopy is based on the absorption of ultraviolet light or visible light by chemical compounds, which results in the production of distinct spectra. Spectroscopy is based on the interaction between light and matter. When the matter absorbs the light, it undergoes excitation and de-excitation, resulting in the production of a spectrum.

You will see that absorption peaks at a value of 217 nm. This is in the ultra-violet and so there would be no visible sign of any light being absorbed - buta-1,3-diene is colourless. You read the symbol on the graph as "lambda-max". In buta-1,3-diene, CH 2 =CH-CH=CH 2, there are no non-bonding electrons. That means that the only electron jumps taking place (within the range that the spectrometer can measure) are from pi bonding to pi anti-bonding orbitals.

The basic spectrophotometer instrument consists of a light source, a digital display, a monochromator, a wavelength sector to transmit a selected wavelength, a collimator for straight light beam transmission, photoelectric detector and a cuvette to place a sample. The intensity of light is symbolized as I 0 measure the number of photons per second. When the light is passed through the blank solution, it does not absorb light and is symbolized as (I).

In UV-visible spectroscopy, wavelength usually is expressed in nanometers (1 nm = 10-9m). It follows from the above equations that radiation with shorter wavelength has higher energy.
