Calculated Value: the Chi-square calc. is obtained by taking the (actual-expected)²/expected for each cell in our problem. Add these up and you have chi-square calc. In this case you have 2 cells, (1) $(56-50)^2/50 = (6)^2/50 = 36/50 = .72$. For cell (2) it equals $(44-50)^2/50 = (-6)^2/50 = 36/50 = .72$. Add cell one and cell two and we get $.72 + .72 = 1.44$. This is Chi-square calculated.

The chi-square test helps us answer the above question by comparing the observed frequencies to the frequencies that we might expect to obtain purely by chance. Chi-square test in hypothesis testing is used to test the hypothesis about the distribution of observations/frequencies in different categories.

What is a Chi-Square Test and How Does it Work?

The chi-squared calculation helps us decide if there is a statistically significant difference between the groups.
