A GREEDY HEURISTIC FOR THE SET-COVERING PROBLEM* V. CHVATAL McGill University Let A be a binary matrix of size $m \times n$, let $c \in \mathbb{R}^n$ be a positive row vector of length n and let e be the column vector, all of whose m components are ones. The set-covering problem is to minimize $c^T x$ subject to $Ax \geq e$ and x binary. We compare the value of the objective function

The greedy algorithm is based on link-rerouting and partial link-rerouting heuristics for the uncapacitated multicommodity network design problem. This algorithm involves a capacity scaling for reducing the number of candidate arcs and a restricted branch-and-bound for improving solutions.

The set-covering problem is to minimize $c^T x$ subject to $Ax \geq e$ and x binary. We compare the value of the objective function at a feasible solution found by a simple greedy heuristic to the true optimum. It turns out that the ratio between the two grows at most

logarithmically in the largest column sum of A . When all the components of cT are the same, our result reduces to a theorem established previously by Johnson and Lovasz.

A greedy algorithm is any algorithm that follows the problem-solving heuristic of making the locally optimal choice at each stage. In many problems, a greedy strategy does not usually produce an optimal solution, but nonetheless a greedy heuristic may yield locally optimal solutions that approximate a globally optimal solution in a reasonable amount of time.

The term "greedy heuristic" actually refers to a class of heuristics, which in general terms go along the following lines: make the first decision based on getting the best "bang for the buck"; recalculate where you are at (needs, capacities, etc.); make the next decision to get best "bang for the buck"; repeat.

Best-first search is known as a greedy search because it always tries to explore the node which is nearest to the goal node and selects that path, which gives a quick solution. Thus, it evaluates nodes

with the help of the heuristic function, i.e., $f(n) = h(n)$.

Although we haven't been able to quickly find optimal solutions to NP problems like the Traveling Salesman Problem, "good-enough" solutions to NP problems can be quickly found [1]. For the visual learners, here's an animated collection of some well-known heuristics and algorithms in action. Researchers often use these methods as sub-routines for their own algorithms and heuristics.

11 Animated Algorithms for the Traveling Salesman Problem

In the study of graph coloring problems in mathematics and computer science, a greedy coloring or sequential coloring is a coloring of the vertices of a graph formed by a greedy algorithm that considers the vertices of the graph in sequence and assigns each vertex its first available color. Greedy colorings can be found in linear time, but they do not in general use the minimum number of colors possible. Different choices of the sequence of vertices will typically produce different colorings of

A greedy algorithm, as the name suggests, always makes the choice that seems to be the best at that moment. This means that it makes a locally-optimal choice in the hope that this choice will lead to a globally-optimal solution. How do you decide which choice is optimal?

The "greedy" heuristic of repeatedly matching the two closest unmatched points can be implemented in worst-case time $O(n^2 \log n)$, a reasonable savings compared to the general minimum weighted matching algorithm which requires time proportional to n^3 to find the minimum cost matching in a weighted graph.
