Once in a while, when reading papers in the Reinforcement Learning domain, you may stumble across mysterious-sounding phrases such as 'we deal with a filtered probability space', 'the expected value is conditional on a filtration' or 'the decision-making policy is $\mathcal{F}_t$ -measurable'. Without formal training in measure theory [2,3], it may be difficult to grasp what exactly such a filtration entails.

Probability Matching and Reinforcement Learning

Empirical laws in the study of animal and human behavior have been the pursuit of behavior analytic psychologists for at least a century. One of the earliest theoretical, empirical laws in the history of behavior analytic psychology is “the law of effect”, credited to E. L. Thorndike at the turn of the 20th century.

One very famous approach to solving reinforcement learning problems is the ϵ (epsilon)-greedy algorithm, such that, with a probability ϵ , you will choose an action a at random (exploration), and the rest of the time (probability $1-\epsilon$) you will select the best lever based on what you currently know from past plays (exploitation).

Probability learning is a principle that states probability of a response tends to match the probability of the reinforcement. How does one achieve such rationality under uncertainty? What are the real-life applications of this concept?

What are the real life applications for Probability Learning?

The idea behind the dynamic programming formulation of reinforcement learning is to choose a policy π , estimate its value function V_π (Algorithm 1), deduce a new policy π' from V_π (Algorithm 2), and iterate this process until a satisfying policy is found (Algorithm 3). This process is known as policy iteration.
