Amorphous semiconductors are
 disordered or glassy forms of crystalline
 semiconductor materials. Like non-
 conducting glasses, they are network
 structures with primarily covalent
 bonding. Crystalline silicon, which has
 the diamond structure, is an ordered
 arrangement of fused six-membered
 silicon rings, all in the "chair"
 conformation, as we saw in Ch. 8.

Transient photoconductivity in
 amorphous semiconductors has received
 much attention because of its specific
 behavior determined by the wide
 distribution of the time constants
 controlling the photocurrent transients.

Multiple trapping of charge carriers by
 localized states, which are quasi-
 continuously distributed in the gap,
 leads to well-known prolonged non-
 stationary processes such as dispersive
 transport and photoinduced transient
 optical absorption.

Amorphous silicon is the non-crystalline
form of silicon used for solar cells and
thin-film transistors in LCDs. Used as
semiconductor material for a-Si solar
cells, or thin-film silicon solar cells, it is
deposited in thin films onto a variety of
flexible substrates, such as glass, metal
and plastic. Amorphous silicon cells

From Wikipedia, the free encyclopedia
Organic semiconductors are solids
whose building blocks are pi-bonded
molecules or polymers made up by
carbon and hydrogen atoms and – at
times – heteroatoms such as nitrogen,
sulfur and oxygen. They exist in form of
molecular crystals or amorphous thin
films.

Amorphous materials are characterised
by lack of order, but can function as

semiconductors with low carrier mobilities. Amorphous silicon, containing hydrogen (aSi:H) is used to make thin film transistors, acting as switches at each pixel point in a LCTV display, thus facilitating matrix addressing. It is also used to make cheap solar cells.
