Aedes albopictus (Stegomyia albopicta), from the mosquito (Culicidae) family, also known as (Asian) tiger mosquito or forest mosquito, is a mosquito native to the tropical and subtropical areas of Southeast Asia; however, in the past few decades, this species has spread to many countries through the transport of goods and international travel [15].

Aedes aegypti is a vector for transmitting several tropical fevers. Only the female bites for blood, which she needs to mature her eggs. To find a host, these mosquitoes are attracted to chemical compounds emitted by mammals, including ammonia carbon dioxide lactic acid, and octenol.

Aedes aegypti - Wikipedia

In Arizona, the return of Ae. aegypti has raised concern about possible dengue outbreaks, particularly as there is active transmission of the disease in the neighboring state of Sonora, Mexico. A curious feature of Ae. aegypti's re-establishment, however, is that presence of the vector does not always lead to dengue virus transmission.

Aedes aegypti presence was positively associated with highly vegetated areas. Other significant variables included microclimatic differences and access to piped water. This study demonstrates the importance of microclimate and human factors in predicting Ae. aegypti distribution in an arid environment.

Understanding the breeding patterns of Aedes aegypti in households and the factors associated with infestation are important for implementing vector control. The baseline survey of a cluster randomised controlled trial of community mobilisation for dengue prevention in Mexico and Nicaragua collected information about the containers that are the main breeding sites, identified possible actions to reduce breeding, and examined factors associated with household infestation.

Aedes aegyptiis among the best-studied mosquitoes due to its critical role as a vector of human pathogens and ease of laboratory rearing. Until now, this species was thought to have originated in continental Africa, and subsequently colonized much of the world following the establishment of global trade routes.

Aedes aegypti (L.) is the primary vector of various infectious viruses such as dengue virus (DENV), yellow fever virus, and chikungunya virus (CHIKV). Because the vector is well adapted to urban environments, poorly planned rapid urbanization partially facilitates the spread of these diseases (Alirol et al. 2011).

Aedes aegypti, the mosquito most commonly associated with spread of Zika and Chikungunya, are essentially ecologically useless disease vectors. Nothing they do in nature wouldn't be done by other creatures except transmit these diseases most often to humans. While much work has been done on Ae. aegypti biology and ecology in urban landscapes, the role of shading on immature stages as an independent factor from temperature, and any possible interactions between these factors, remains unexamined. We assessed how temperature and shading affected egg hatch-rate, larval/pupal mortality, and larval development to adult stage under different factorial temperature (28; 31; 34; 37; 40° C) and shade (0%, 3,100 lux; 40%, 1,860 lux; 75%, 775 lux; 100%, 0 ...

All experiments were performed with male mosquitoes Aedes aegypti (4-10 days post emergence), from the laboratory population of the Harrington Laboratory (Department of Entomology, Cornell University). The colony was established from eggs collected in Tapachula, Mexico (14°54'N, 92°15'W) in 2006, subsequently supplemented from eggs collected from the same region in 2008 and 2009.

The Long and Short of Hearing in the Mosquito Aedes aegypti

The yellow fever mosquito (Aedes aegypti), is the primary vector of dengue, Zika, and chikungunya fever, among other arboviral diseases. It is also a popular laboratory model in vector biology due to its ease of rearing and manipulation in the lab. Established laboratory strains have been used worldwide in thousands of studies for decades.

Zika, dengue, chikungunya, and yellow fever are all transmitted to humans by the Aedes aegypti mosquito. More than half of the world’s population live in areas where this mosquito species is present. Sustained mosquito control efforts are important to prevent outbreaks from these diseases.

This review focuses on the ecology and nongenetic control of the domestic variety of Aedes aegypti, the main vector of dengue viruses worldwide. Factors limiting the application of control measures against Aedes aegypti mosquitoes, including genetic control approaches, are discussed.

Considerations for Disrupting Dengue Virus Transmission ...

Aedes aegypti abundance indoors and outdoors varied in proportion to human density and land area, respectively, which indicated that the built environment and neighborhood layout influenced Ae. aegypti habitat suitability. Increased population density was associated with reduced Ae. aegypti abundance indoors. The negative correlations between population density and potted plants and containers of standing water indoors could explain this finding.

In the present study, the effects of two spatial repellents (SR) were determined for Aedes aegypti and Ae albopictus, the main vectors of dengue, Chikungunya, and Zika fever. The modular high-throughput screening system (HITSS) was used to evaluate the response of both species to transfluthrin and linalool SR at different concentrations.
