Pressure-induced structure transitions occur at pressures of 2.3–6.6 GPa, ~8.5 GPa, and ~17.7 GPa. The phase transition at 2.3–6.6 GPa is related to the rotation of NH₂, and the latter two transitions are caused by both the rotation of NH₂ and the distortion of the heterocycle.

Understanding phase transitions and post-inflationary dynamics ('preheating') requires powerful non-perturbative techniques in field theory, pre-eminently, real-time lattice field theory. For the foreseeable future, real-time lattice field theory means field theory in the classical approximation, which holds when temperatures and densities are high.

The term phase transition is most commonly used to describe transitions between solid, liquid, and gaseous states of matter, as well as plasma in rare cases. A phase of a thermodynamic system and the states of matter have uniform physical properties. During a phase transition of a given medium, certain properties of the medium change, often discontinuously, as a result of the change of external conditions, such as temperature, pressure, or others. For example, a liquid may become gas upon heating.
