A differential form is a linear transformation from the vector fields to the reals given by $\alpha = \sum_{i=1}^n a_i dx_i$. (1.2) We identify a vector field v with the corresponding directional derivative $v = \sum_{i=1}^n v_i \partial/\partial x_i$. (1.3) The value of α on the vector field v is $\alpha \cdot v = \sum_{i=1}^n a_i v_i$. (1.4) If z is a scalar function on M , then it has a differential given by $dz = \sum_{i=1}^n \partial z/\partial x_i dx_i$.

Vector calculus can be defined on other 3-dimensional real vector spaces if they have an inner product (or more generally a symmetric nondegenerate form) and an orientation; note that this is less data than an isomorphism to Euclidean space, as it does not require a set of

coordinates (a frame of reference), which reflects the fact that vector calculus is invariant under rotations (the special ...

But differentiation $\frac{d}{dx}$ is a linear operator (a fancy name for a linear map between function spaces) from the vector space of differentiable functions to the vector space of functions. This is important, but it's something else entirely, and not related to the "total derivative" and "Jacobian" etc that you were asking about. \$endgroup\$ - aes May 1 '15 at 4:42
