Traffic Control Devices Handbook

"The purpose of the Traffic Control Devices Handbook (the Handbook or TCDH) is to augment the Manual on Uniform Traffic Control Devices for Streets and Highways (the Manual or MUTCD), as adopted nationally by the United States Federal Highway Administration (FHWA). The Manual outlines the design and application of traffic control devices on roadways in the United States. However, criteria and data to make decisions on the use of a device and its application are not always fully covered in the Manual. This Handbook bridges the gap between the Manual provisions and those decisions to be made in the field on device usage and application"--Provided by publisher.

Establishment of Local Trip Generation Rates Or Equations for Mixed-use Developments in Kansas

Currently, the trip generation rates and equations contained in the Institute of Transportation Engineers (ITE) Trip Generation Manual, 8th Edition are based on the information collected at single-use, free-standing sites and cannot be directly applied to multi-use developments. Application of this data for multi-use development sites requires use of an adjustment factor called "internal capture rate", which is expressed as a percent reduction to the trips generated by individual land uses. These reductions are applied externally to the site at the entrances, adjacent intersections and roadways. They are distinct and separate from "pass-by" and "diverted-link" trips and are applied before "pass-by" and "diverted-link" trip reductions are applied. While the trip generation rates for individual uses on a multi-use development site may be the same or similar to what they are for free-

standing sites, there is potential for interaction between among those uses within the site, particularly where the trip can be made by walking. As a result, the total generation of vehicle trips entering and exiting the multi-use site may be reduced from simply a sum of the individual, discrete trips generated by each land use. Because the development of mixed-use or multi-use sites is increasingly popular, ITE wishes to increase the database on multi-use developments in order to provide internal capture data for a broader range of land uses. ITE would appreciate additional data from analyses of such developments. The goal of this research project is to establish a local trip generation rate model for multi-use developments in state of Kansas, which can potentially be submitted to the ITE headquarter for inclusion in the national database as well. The primary objectives were to identify several appropriate multi-use development sites in the state and document vehicular trip data generated by each site in order to develop a trip generation model that can be used to better estimate trip numbers generated by such sites. A total of three sites were selected and studied for this project including "Mission Farms" and "Park Place" developments, both in Leawood, Kansas; and "Metcalf95 Complex" in Overland Park, Kansas.

This research examines the effects of town centers and senior housing developments on surrounding roadways and nearby transit. The Institute of Transportation Engineers (ITE) Trip Generation Manual, which determines number of trips produced or attracted by different developments, does not include town centers. It has also been argued that the ITE manual underestimates trip rates for senior housing. This, coupled with the prominence of these types of developments in Maryland, merits further study into their impacts on the surrounding roadway system.

Enhancing Internal Trip Capture Estimation for Mixed-use Developments *Transportation Research Board*

TRB's National Cooperative Highway Research Program (NCHRP) Report 684: Enhancing Internal Trip Capture Estimation for Mixed-Use Developments explores an improved methodology to estimate how many internal trips will be generated in mixed-use developments - trips for which both the origin and destination are within the development. The methodology estimates morning and afternoon peak-period trips to and from six specific land use categories: office, retail, restaurant, residential, cinema, and hotel. The research team analyzed existing data from prior surveys and collected new data at three mixed-use development sites. The resulting methodology is incorporated into a spreadsheet model, which is available online for download.

Access Management Manual

"Since the publication of the first edition of the Access Management Manual, the context for transportation planning and roadway design in the United States has been transformed. Transportation agencies and local governments are under growing pressure to integrate land use and transportation policy and achieve a more sustainable, energy-efficient transportation system. This second edition of the manual responds to these developments by addressing access management comprehensively, as a critical part of network and land use planning. The content is interdisciplinary, with guidance pertinent to various levels of government as well as to pedestrians, bicyclists, and motorized vehicles, including trucks and buses, and is strongly grounded in decades of research, engineering science, and professional experience. Greater emphasis is placed on appropriate location of access, and guidance is refined to provide appropriate consideration of context and community issues. Substantial updates aid state and local agencies in managing access to corridor development effectively. Specific guidance on network and circulation planning and modal considerations is included, as well as guidance on effective site access and circulation design. A chapter on corridor management reinforces these concepts with a framework for application of access management in different contexts, along with appropriate strategies for each context. There are also new chapters on network planning, regional access management policies and programs, interchange area access management, auxiliary lane warrants and design, and right-of-way and access control. The manual concludes with an extensive menu of access management techniques and information on their application"-- Provided by publisher.

Smart Growth Trip Generation of Coffee Shops

Smart growth developments are high density developments which have a mix of land uses like residential, retail, commercial for example, on the same location thereby providing good potential for interaction between them. Due to the proximity of these different land uses, there exists convenience for other modes of transport like walking, biking and the use of transit. The ITE Trip Generation manual, which has been the traditional source of trip generation data, is mostly based on suburban dispersed study sites where there is limited potential for using other modes of transport other than automobile. Therefore, relying on the conventional ITE Trip Generation manual for estimating trip generation rates for smart growth areas do not produce accurate results. Using suburban development trip rates for smart growth settings might overestimate the trip generation rates resulting in more transportation infrastructure than required. This project focuses on establishing the trip generation rates for smart growth settings in California focusing on the land use coffee shops and creates a mode share database of the different trips generated. The total vehicle trips from this study are compared with standard ITE trips to see if there are any differences in the rates. The methodology adopted in this study utilizes the same methodology adopted by Caltrans for the study on trip generation in urban infill areas and by UC Davis for the study on smart growth trip generation in California. The methodology uses a combination of intercept survey and in and out door counts to determine the trip generation rates of coffee shops. This methodology counts the trips generated by walking, biking and transit in addition to auto trips. It also helps in calculating the auto trip generation which uses shared parking and off-street parking which is common in smart growth sites. Six coffee shops in and around San Jose, California were chosen as study sites, and data were collected in May 2013. The responses from intercept surveys were combined with door count data to estimate the peak-hour trips along with the mode share during the peak hour. Results reveal that on an average, ITE overestimates peak-hour trips by 34% during the AM peak hour and by 18% during the PM peak hour at smart growth coffee shops. There is also a noticeable contribution of trips by other modes such as walk (24%), bike (2%) and transit (2%). As smart growth developments are becoming more and more popular, future studies with more sites focusing on a particular land use is recommended to gather more identified trip generation results of smart growth sites.
