Calibration in analytical chemistry refers to the relation between sample domain and measurement domain (signal domain) expressed by an analytical function $x = f_s(Q)$ representing a pattern of chemical species Q and their amounts or concentrations x in a given test sample on the one hand and a measured function $y = f(z)$ that may be a spectrum, chromatogram, etc.

Simultaneous multispecies analyses are carried out mainly by spectroscopic and chromatographic methods in a more or less selective way.

As previously mentioned, the term

analytical calibration is used when the calibration process cannot be performed directly. In general, the objective of doing calibration is to establish an experiential liaison between the instrument response signal “y-variable” and the reaction factors “x-variable.” The purpose of establishing such a liaison is to be able to assess the influence of these variables on the response and hence quantify the analyte.
