The Reynolds-stress measurements demonstrate that the turbulence structure of the separated shear layer differs from that of a plane mixing layer between two streams in a number of ways. In particular, the normal stresses all rise monotonically as reattachment is approached, are always considerably higher than the plane layer values and develop in quite different ways.

When the gap ratio is above $G/H=0.2$, the turbulence statistics have large values in the lower shear layer. For the gap ratio $G/H \leq 0.1$, however, the lower shear layer displays small turbulence-statistics values and approach those of the no-gap case ($G/H=0$) with increasing distance downstream. In the upper shear layer separated from the fence top, the turbulence statistics are nearly independent of the gap ratio.
