Seismic Filtering

Filtering of Seismic Data. The interpretation of seismic data is made purely on the basis of what is observed in the final processed section. CMP processing greatly enhances the signal to noise ratio and allows coherent reflections to be visible. However, the data that goes into the CMP processing is often contaminated with “noise”.

Filtering of Seismic Data — GPG 0.0.1 documentation

Filtering is used in seismic data processing to enhance the signal quality by suppressing undesirable acquisition

or processing noise or artifacts which can alter seismic data (i.e. seismic attributes such as velocities or amplitudes).

F-k filtering is when seismic data, that is traditionally in the time and displacement domain, is converted into the frequency and wave number (F-k) domain as seen in figure 1 below. The

seismic data is then filtered to remove unwanted frequencies higher and/or lower than the seismic signal band, and then converted back to the time-displacement domain. The process is a two dimensional Fourier transformation and must be sampled according to the Nyquist criterion to avoid aliasing.

F-k filtering - SEG Wiki

Seismic inverse Q filtering is a data processing technology for enhancing the resolution of reflection seismology images. Q is the anelastic attenuation factor or the seismic quality factor, a measure of the energy loss as the seismic wave moves.

Seismic inverse Q filtering - Wikipedia

A zero-phase band-limited wavelet can be used to filter a seismic trace. The output trace contains only those frequencies that make up the wavelet used in filtering. The time-domain representation of the wavelet is the filter operator. The individual time samples of this operator are the filter coefficients. The process described here is zero-phase frequency filtering, since it does not modify the phase spectrum of the input trace, but merely band-limits its amplitude spectrum.

Frequency filtering - SEG Wiki

In practice, band-limited wavelets are used to filter the seismic data, which are known as filter operators in the time domain, and amplitude samples of this operator are termed filter coefficients.

The most practical filter operator to be used for frequency filtering is determined by the Fourier transform theory.

Filtering can be used to separate out a particular seismic event, which is shown

on the seismic section, using apparent velocity as the selection criterion. Each straight-line event, like a direct wave, refracted wave or surface wave, has a particular apparent velocity.

filter | Oilfield Glossary

Seismic processing attempts to enhance the signal to noise ratio of the seismic section and remove the artifacts in the

signal that were caused by the seismic method. The end result should be a more interpretable section. The process has some very subjective elements.

In response to this need a post-stack structurally oriented coherent noise filtering process has been developed and is described, with an application to 3D seismic surveys from the North Sea. The

results are evaluated by comparing seismic volumes, edge attribute volumes, and amplitude and phase spectra pre- and post-filtering.

Structurally oriented coherent noise filtering

During seismic wave propagation in attenuation medium, the energy of signal components seriously decreases, especially those with higher frequencies. The seismic attenuation and resolution reduction are generally compensated for with inverse Qfiltering in the frequency or time domain.

Collaborative filtering is the next sub-step that denoise seismic data in the 3D transform domain. Unlike the common transform method, a 2D operator is first applied to the matched blocks and a 1D operator will then be implemented along the vertical direction to get the transform result Vf.
