Scientists use various methods to study DNA-protein interactions, but Spelios pointed out that one of the most popular methods is chromatin immunoprecipitation followed by sequencing . “The main limitation of ChIP-Seq is that it requires a large amount of input material—cells or tissue

to produce a strong enough signal over background noise—as well as the use of cross-linking during an initial fixation step,” he said.

DNA-binding proteins are proteins that have DNA-binding domains and thus have a specific or general affinity for single- or double-stranded DNA. Sequence-specific DNA-binding proteins generally interact with the major groove of B-DNA, because it exposes more functional groups that identify a base pair. However, there are some known minor groove DNA-binding ligands such as netropsin, distamycin, Hoechst 33258, pentamidine, DAPI and others.
