How to Compare Two Independent Population Averages

When comparing two population proportions, we start with two assumptions: The two independent samples are simple random samples that are independent. The number of successes is at least five and the number of failures is at least five for each of the samples. Comparing two proportions (e.g., comparing two means) is common.

Weight is a dependent variable because it depends on the other variables - taller people tend to be heavier; men tend to be heavier than women, and so on. But the data are independent if the weight and other variables for one person aren't related to those for another. Sometimes, though, the data are dependent .

test is used when you're looking at a numerical variable - for example, height - and then comparing the averages of two separate populations or groups (e.g., males and females).

T-Test Calculator for 2 Independent Means

Each person's opinion is independent of the others, so we have independent data. From Table 2 we should use a χ^2 test for trend, or a Mann-Whitney U test with a correction for ties (N.B. a tie occurs where two or more values are the same, so there is no strictly increasing order of ranks - where this happens, one can average the ranks for tied values).
