The use of linear mixed effects models (LMMs) is increasingly common in the analysis of biological data. Whilst LMMs offer a flexible approach to modelling a broad range of data types, ecological data are often complex and require complex model structures, and the fitting and interpretation of such models is not always straightforward.

Variables can be defined at any level and the study of those variables and their interactions is generally known as multilevel or mixed-effects modeling. Mathematically, mixed-effects models can be seen as a hierarchical system of regression equations where L1 parameters are function of the L2 equations. The following equations represent a two-level model with one L1 predictor, X, and one L2 predictor, W. Level-1: $Y_{ij} = \beta_{0j} + \beta_{1j}X_{ij} + r_{ij}$

Linear mixed effects models are powerful yet complex tools. Software advances have made these tools accessible to the non-expert and have become relatively straightforward to fit in widely available statistical packages such as R (R Core Team, 2016). Here we focus on the implementation of LMMs in R, although the majority of the techniques covered here can also be implemented in alternative packages including SAS (SAS Institute, Cary, NC, USA) & SPSS (SPSS Inc., Chicago, IL, USA).

Mixed Models: Introduction

Mixed Effects Model can be used to model both linear and nonlinear relationships between dependent and independent variables. The Mixed Modeling framework can specify a variety of model types including random coefficients models, hierarchical linear models, variance components models, nested models, and split-plot designs.

Introduction to Linear Mixed Models

Mixed-effects models include both random and fixed effects. The variables that are included as fixed effects in the models are either co-variates or factors. Co-variates are numerical variables such as frequency; factors are categorical variables with a fixed and low number of levels which exhaust the levels in the sampled population.
