The phase diagram shows, in pressure-temperature space, the lines of equilibrium or phase boundaries between the three phases of solid, liquid, and gas. The curves on the phase

diagram show the points where the free energy (and other derived properties) becomes non-analytic: their derivatives with respect to the coordinates (temperature and pressure in this example) change discontinuously (abruptly).

The phase equilibrium of the mixed-phase regions is driven by the Gibbs enthalpy of the phase mixture: $G = x_1G_1 + x_2G_2$, where x_i are the molar fractions of the two phases and G_i their Gibbs enthalpies. The equilibrium condition requires that the total Gibbs enthalpy remains unchanged: $dG = G_1dx_1 + G_2dx_2 = 0$.

The phase rule is a general principle governing "pVT systems" in thermodynamic equilibrium, whose states are completely described by the variables pressure (p), volume (V) and temperature (T). If F is the number of degrees of freedom, C is the number of components and P is the number of phases, then $F = C - P + 1$. It was derived by Josiah Willard Gibbs in his landmark
