Partial Face Recognition Using RPSM Algorithm

After face alignment, partial face recognition is achieved by measuring face similarity based on the proposed point set distance, which can be readily acquired with the face alignment result. The hallmark of the RPSM is its robust matching scheme, which considers both the geometric distribution consistency and the textural similarity.

In this paper, we propose a general partial face recognition approach that does not require face alignment by eye coordinates or any other fiducial points. We develop an alignment-free face representation method based on Multi-Keypoint Descriptors (MKD), where the

descriptor size of a face is determined by the actual content of the image.

Finally, it achieves partial face recognition using region-to-region matching. Although MR-CNN achieves remarkable performance on several partial face databases, the computational cost is extensive because it repeatedly runs a deep convolutional network for each sub-region proposal.

Facial recognition is the task of making a positive identification of a face in a photo or video image against a pre-existing database of faces. It begins with detection - distinguishing human faces

from other objects in the image - and then works on identification of those detected faces. The state of the art tables for this task are contained mainly in the consistent parts of the task : the ...
