The proportionality constant, K_f , is called the molal freezing-point depression constant. It is a constant that is equal to the change in the freezing point for a 1-molal solution of a nonvolatile molecular solute. For water, the value of K_f is $-1.86^\circ\text{C}/m$. So the freezing temperature of a 1-molal aqueous solution of any nonvolatile molecular solute is -1.86°C .

ΔT is the freezing point depression, K_f is the freezing point depression constant (in this case it's $20.2^\circ\text{C}/m$), and m is the molality of the solution. In this lab the first thing we need to do is determine the ΔT . This can be done by using the following equation: $\Delta T = T_1(\text{pure liquid}) - T_2(\text{mixed liquid})$.

Lab: Freezing Point Depression Flashcards | Quizlet

The freezing point depression can be calculated by the formula: $\Delta T_f = i \times K_f \times m$ In this equation, ΔT_f is the freezing point depression, K_f is the freezing point depression constant, and i is the van 't Hoff factor. The freezing point depression constant changes depending on the solvent, and the van 't Hoff factor accounts for the number of particles that a dissolving solute creates in solution.

The freezing point depression says that the freezing point of a mixture of two components is lower than that of individual components. It involves a solvent (e.g. water) and a solute which you'll mix with the solvent. A very common example of this phenomenon in everyday life is salting of the roads in water. Pure water freezes at 0°C .

Freezing point depression can be calculated using the Clausius-Clapeyron equation and Raoult's law.

In a dilute ideal solution, the freezing point is: Freezing Point total = Freezing Point solvent - ΔT_f , where $\Delta T_f = \text{molality} \times K_f \times i$.

What Freezing Point Depression Is and How It Works

The experimental van't Hoff factor of MgCl_2 was found by conducting freezing point depression trials. Three ice baths were made up in 500 mL beakers using ice, approximately 50 mL of water, and around 10 g of rock salt (NaCl). Additional rock salt was added as needed until the temperature of the baths reached -10°C .

Physically, freezing point depression and boiling point elevation occur because a solution consisting of a solvent (the formerly pure liquid) with a small amount of solute added is thermodynamically more stable than the pure liquid itself—primarily due to the fact that the addition of the solute increases the entropy of the solution.
