The relation is now  $Y = X B$ . In MATLAB, you can find B using the `mldivide`

operator as  $B = X \backslash Y$ . From the dataset accidents, load accident data in y and state population data in x. Find the linear regression relation  $y = \beta_1 x$  between the accidents in a state and the population of a state using the \ operator.

The linearity in a linear regression model refers to the linearity of the predictor coefficients. Use the properties of a LinearModel object to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data.

$b = \text{regress}(y,X)$  returns a vector b of coefficient estimates for a multiple linear regression of the responses in vector y on the predictors in matrix X. To compute coefficient estimates for a model with a constant term (intercept), include a column of ones in the matrix X. [b,bint]

= regress(y,X) also returns a matrix bint of 95% confidence intervals for the coefficient estimates.

Linear Regression Prepare Data. To begin fitting a regression, put your data into a form that fitting functions expect. All regression techniques begin with input data in an array X and response data in a separate vector y, or input data in a table or dataset array tbl and response data as a column in tbl.

A very difficult concept to grasp is the difference between a confidence interval and a prediction interval for a simple linear regression model, so the next part of the MATLAB Live Script mathematically describes the difference
