The oxide phase present in the material and preferred pathways for local cracking and separation have been determined. Thin intersplat oxide layers emerge as preferential sites. These oxides are amorphous and the cracks extend along the oxide/ α -Fe interfaces with low local fracture toughness, in the range 0.2-1 MPa $\sqrt{m}$.

Microstructure Deformation And Cracking Characteristics

Abstract The microstructure and local mechanical characteristics of thermal spray ferrous coatings have been determined. The emphasis has been on coatings made by the high velocity oxyfuel (HVOF) process, especially the role of Al alloy additives. The oxide phase present in the material and preferred pathways for local cracking and separation have been determined.

The microstructure analysis indicates that a small amount of graphite precipitated flaky hard martensite, and lower bainite remains in this area. Deep grooves are induced by the separation of graphite from the fracture. Characteristics of intergranular fracturing are evident in micromorphological analysis.

It reveals that the damage initiates by brittle cracking of blocky primary Si and intermetallic particles as marked by the arrows in Fig. 7a. Those cracks can be considered as micro-crack formation. It should be noticed that the cracking begins to occur at a low stress of 139 MPa in contrast with the fracture stress of 200 MPa.

The effect of thermal exposure on the microstructure and ...

This result can be explained as follows. First, different deformation types induce different deformed microstructures, and the recrystallized microstructure also presents differences. Second, the LAGBs are a type of defect that accumulates energy. During tension, the deformation energy is released by cracking.

Cold deformation of low-carbon steels transforms a martensite structure to a submicrocrystalline one at much lower plastic strain degree values in comparison with deformation of initial ferrite-cementite microstructure [2, 3]. The produced structure is characterized by smaller grain size and much higher hardness values.

For stainless steels, the microstructures are similar in that the failure is by grain-boundary-sliding and crack formation. In a superheater or reheater tube, often the very first sign of creep damage is longitudinal cracks in the steam-side scale. As creep deformation expands the tube diameter, the brittle ID scale cannot follow the expansion.
