Single image super-resolution (SISR) is a notoriously challenging ill-posed problem, because a specific low-resolution (LR) input can correspond to a crop of possible high-resolution (HR) images, and the HR space (in most instances it refers to the nature image space) that we intend to map the LR input to is usually intractable.

In image super-resolution, we need to feed a blurry image and clean high-resolution to the neural network. The blurry image acts as the input data and the high-resolution image acts as the input label. With each iteration, the deep neural network tries to make the blurry images look more and more like the high-resolution images.

ESPCN (Efficient Sub-Pixel CNN), proposed by Shi, 2016 is a model that reconstructs a high-resolution version of an image given a low-resolution version. It leverages efficient "sub-pixel convolution" layers, which learns an array of image upscaling filters.

Image Super-Resolution using an Efficient Sub-Pixel CNN

Image super-resolution (SR) is a fundamental ill-posed problem in low-level vision that reconstructs a high-resolution (HR) image from its low-resolution (LR) observation.

Recent progress in the on deep learning-based methods has significantly improved the performance of SR, increasing attention from the practical perspective.

In general, thermal images have a poor resolution, which could

be improved by using learning-based traditional super-resolution methods. These methods have been largely used in the visible spectral domain. They work by downsampling and adding noise and blur to the given image.

Super resolution is simply the upscaling of lower resolution images into a higher resolution, without updating or changing the hardware of your device. Researchers are exploring neural networks that can estimate how a low resolution image would look in a higher resolution and display that estimation in real-

time.
