Protein synthesis is a two-step process that involves two main events called transcription and translation. In transcription, the DNA code is transcribed (copied) into mRNA. Once the mRNA is

produced it moves out of the nucleus into the cytoplasm where it links up with ribosomes (protein making organelles) and begins churning out proteins.

The process of converting the information in DNA into protein is a two-step process, involving transcription and translation. In transcription, an mRNA copy is made of the

DNA. In translation, the mRNA travels to a ribosome, where tRNAs bring the matching amino acids together to form a protein. The primary aim of the lab is:

DNA To Protein | Golabz

From DNA to protein - 3D The use of DNA during protein synthesis takes place in the first stage called amino acid synthesis. The second stage is called transcription, and the final phase is where the ribosome translates the information into protein. A protein called helicase splits apart both polymers of DNA in protein synthesis.

From Dna To Protein Synthesis Lab Answers

In all living cells, the process of translating genetic information from DNA into the proteins that do most of the work in a cell is carried out by molecular machines made of a combination of RNA and protein. Surprisingly, it is the RNA, and not the protein, that does the critical work in this protein-making machine, which is called the ribosome.
