Growth Factors And Wound Healing

Part I of this two-part series presents an overview of the biochemical properties of five families of peptide growth factors that are thought to be involved in wound healing: epidermal growth factor (EGF), transforming growth factor-beta (TGF-beta), platelet-derived growth factor (PDGF), insulin-like growth factor (IGF), and fibroblast growth factor (FGF).

Growth Factors and Wound Healing: Biochemical Properties ...

Objective: We will discuss the biology of growth factors and the dramatic effects these proteins have on cell proliferation, cell chemotaxis, and on the formation of extracellular matrix molecules. Results: Growth factors are extremely potent biologic agents that show promise in accelerating wound repair in both animal and human studies. They improve granulation tissue, enhance tensile strength, and promote reepithelialization.

Wound healing, therefore, is divided into three phases: (1) inflammation, (2) fibroplasia, and (3) maturation. 9 Each of these phases is controlled and regulated by biologically active substances called growth factors. Growth factors are polypeptides that control the growth, differentiation, and metabolism of cells. 16 These growth factors are hormone-like molecules that interact with specific cell surface receptors to control the process of tissue repair. 7 Although they are present in only ...

THE ROLE OF GROWTH FACTORS IN WOUND HEALING - ScienceDirect

For the last decade, it has been acknowledged that growth factors are essential for regulating the cellular events involved in the formation of granulation tissue and in wound healing. Recently, clinical trials were initiated to study the wound healing effect of applying growth factors and growth hormone to human wounds.

The migration, infiltration, proliferation, and differentiation of these cells will culminate in an inflammatory response, the formation of new tissue and ultimately wound closure. This complex process is executed and regulated by an equally complex signaling network involving numerous growth factors, cytokines and chemokines.

Growth factors and cytokines in wound healing

The success of the wound healing process depends on growth factors, cytokines, and chemokines involved in a complex integration of signals that coordinate cellular processes. These agents are biologically active polypeptides that act to alter the growth, differentiation and metabolism of a target cell.

The fluid engorgement allows healing and repair cells to move to the site of the wound. During the inflammatory phase, damaged cells, pathogens, and bacteria are removed from the wound area. These white blood cells, growth factors, nutrients and enzymes create the swelling, heat, pain and redness commonly seen during this stage of wound healing.
