In this model, we assume there exists an oracle: h : such that on input: $x \in \{0, 1\}^*$, if h has not seen x before, then it outputs a random value as $h(x)$. Otherwise, it returns $h(x)$ it previously output.

Universal hashing, we're going to guarantee there are very few conflicts in expectation. Perfect hashing, we're going to guarantee there are zero conflicts. The catch is, at least in its obvious form, it only works for static sets. If you forbid, insert, and delete and just want to do search, then perfect hashing is a good method.

Hashing is the process of creating a short digest (i.e., 64 bits) for a message of arbitrary length, for example 20 Mbytes. Hashing algorithms were first used for searching records in databases; they are central for digital signature applications and are used for authentication without secrecy. Covering all practical and theoretical issues related to the design of secure hashing algorithms the book is self contained; it

includes an extensive bibliography on the topic.

A hashing algorithm is a cryptographic hash function. It is a mathematical algorithm that maps data of arbitrary size to a hash of a fixed size. A hash function algorithm is designed to be a one-way function, infeasible to invert. However, in recent years several hashing algorithms have been compromised.

In the second week of this course, we'll learn about cryptography. We'll explore different types of encryption practices and how they work. We'll show you the most common algorithms used in cryptography and how they've evolved over time. By the end of this module, you'll understand how symmetric encryption, asymmetric encryption, and hashing work; you'll also know how to choose the most appropriate cryptographic method for a scenario you may see in the workplace.
