If emitted photons are in the visible region of the spectrum, they may be perceived as lines of different colors (note that photons outside the visible spectrum may also be emitted, but cannot be seen). The result is called a line emission spectrum, and can serve as a 'fingerprint' of the element to which the atoms belong. For example, the line spectra shown below for the elements helium and carbon are clearly quite different (colors can be seen in the PDF document online).

Energy is emitted in the form light energy (brightly colored lines) when the electron "falls" from a higher to a lower energy level (higher to lower value of "n"). The energy thus emitted is also equal to $DE = E_{\text{final}} - E_{\text{initial}}$. Summing up the two situations, gives: Chemistry 101 Page 115 of 191.

Herschel's discovery of emission spectra from heated gas was studied extensively in the 1800's. It was

realized that a heated gas emits a unique combination of colors, called emission spectrum, depending on its composition. Example: Helium gas in a discharge lamp. Main idea: put a large voltage across the gas. It will break down and emit light.

Hydrogen Model: The relation between the energy and the wavelength of the emitted light is: E (electric volts eV) = $12,400 \lambda$ (Angstroms) . By studying the hydrogen model, we can see that the electron's jumps from one orbit to another produce the light visible on the spectrum.

Abstract - Home | Department of Physics and Astronomy

Using spectroscopy (also called spectral analysis, spectrometry, or spectrophotometry), we will examine emission and absorption of light by

various substances. Spectrometers (also called spectrophotometers) are measurement tools designed to distinguish different colors of light. The spectrometers we

will use in this lab detect the intensity of the light (the power-per-area associated with the light) as a function of the wavelength of the light.
